within alanine peptides linked to short proline arms. (1) Two peptides were employed in our studies, OO-T**-FPFP**-OOG and OO-T**-FPFPAAA-OOG, where O is Omithine, T** is Toce (2,2,6,6-Tetramethylpyperidin-1-oxyl-4-amino-4-carboxylic acid), A** is 15N labelled alanine. Mesostate based Monte-Carlo sampling calculations (2) were carried out to interpret the relaxation data. The conclusion of the study is that over 90% occupation of extended conformations, i.e. PII and β mesostates, is required to reproduce the experimentally observed distance averaging. Compact structures including βαL and βαL and turns are clearly present but are not dominant in the conformational ensemble. Analysis of the conformation of the side chains will be presented.

A Solution NMR and Crystallographic Study of the Role of the Quaternary Shift in the Allosteric Regulation of Phosphofructokinase from B. stearo-
thermophilus
Texas A&M Univ. College Station, TX, USA.
The 136 kDa Bacillus stearothermophilus phosphofructokinase (BsPFK) is a homotetramer that is allosterically inhibited by phosphoenolpyruvate (PEP), which binds along one dimer-dimer interface. Fru-6-P binds along the other. The substrate bound and the inhibitor bound structures of wild-type BsPFK exhibit a 7° rotation about the substrate binding site interface, termed the quaternary shift. The binding of substrate and inhibitor to BsPFK have been studied using 1H-15N TROSY NMR. The structure of the BsPFK monomer with 13C3H13 in an otherwise fully deuterated enzyme, only the Ile are detected on a 2D-1H-15C correlation spectrum. Several distinct Ile cross-peaks change position when PEP is added to wild-type apo BsPFK. To distinguish between changes associated with the quaternary shift and those associated with intra-subunit tertiary changes, the variant D12A BsPFK is currently being studied using kinetics, x-ray crystallography, 1H-15N TROSY NMR. When compared to wild-type, D12A BsPFK shows a 100-fold increase in the binding affinity for PEP, a 50-fold decrease in the binding affinity for F6P, and an allosteric binding comparable to wild-type. Crystal structures of apo and PEP bound forms of D12A BsPFK both indicate a shifted structure similar to the inhibitor bound structure of wild-type. Since PEP still inhibits D12A BsPFK substantially despite the fact that it has already adopted the inhibited quaternary structure, the inhibition likely involves further tertiary changes to the enzyme. NMR of deuterated, 13C3H13 labeled D12A is being performed in an otherwise fully deuterated matrix. NMR and 15N chemical shift analysis of the conformation of other side chain will be presented. Supported by grant GM33216 from NIH and grant A1543 from the Welch Foundation.

From Data or Dogma? The Myth of the Ideal Helix
Washington University in St. Louis, Saint Louis, MO, USA.
In the course of building detailed surface representations for peptidomimetics, we were motivated to analyze the detailed surfaces of helices in proteins. Unexpectedly, we observed that the few ideal helical forms that have been studied using隐约 crystallography, 1H-15N TROSY NMR. When comparing to wild-type, D12A BsPFK shows a 100-fold increase in the binding affinity for PEP, a 50-fold decrease in the binding affinity for F6P, and an allosteric binding comparable to wild-type. Crystal structures of apo and PEP bound forms of D12A BsPFK both indicate a shifted structure similar to the inhibitor bound structure of wild-type. Since PEP still inhibits D12A BsPFK substantially despite the fact that it has already adopted the inhibited quaternary structure, the inhibition likely involves further tertiary changes to the enzyme. NMR of deuterated, 13C3H13 labeled D12A is being performed in an otherwise fully deuterated matrix. NMR and 15N chemical shift analysis of the conformation of other side chain will be presented. Conformation Coupling Between The I-like Domain Alpha? Helix And The Hybrid Domain Of Beta3 Integrins
Georgia Institute of Technology, Atlanta, GA, USA.
Integrins are zβ heterodimers that mediate cell adhesion and transduce signals bidirectionally across the cell membrane. Integrins often exist in low affinity (or inactive) states for ligand binding on the cell surface, but change conforma-
tions to high affinity (or activated) states when induced by stimuli from inside or outside the cell. Crystallographic and electron microscopic studies have ob-
tained evidence that the low affinity states correspond to bent conformations where the integrin headpiece interacts with the legs, whereas the high affinity states correspond to more extended conformations where integrins stand up, suggesting a switchblade-like unbinding model for integrin activation. In this model, the key conformational changes on integrin headpiece include the swing out of the hybrid domain and the downward movement of I-like do-
main zα helix. These conformational changes are suggested by crystal struc-
tures of β3 integrin headpieces. The unliganded zβ, headpiece displays a closed hybrid domain with the I-like zα helix in an upper position and the pseudo-ligated zββ helix shows an open hybrid domain with the I-
like zα helix in a lower position. Using molecular dynamics simulations we studied the stability of the two conformations of the I-like domain zα helix and the hybrid domain, the transition between the two conformations in each structure, and the opening between the conformational changes in the two structures. We observed that the z-propeller domain of the zα subunit helped sta-
bilize the hybrid domain at the close conformation. The down/upward move-
ments of the I-like zα helix correlated with the opening/closing of the hybrid domain. Our simulations identify key residues to the zα helix movement and suggest the existence of intermediate conformations of the hybrid domain between the open and the close conformations.

The Parkinson’s disease-related protein alpha-Synuclein (αS) is a 140 residue pro-
tein that is natively unfolded in solution. Its membrane-binding properties are implied in its physiological or pathologic activity. αS was investigated by spin-label EPR. By Electron-Electron Double Resonance (DEER) the distance between the spinlabels in four double mutants was determined in the vesicle-bound and free form of αS, revealing antiparallel arrangement of the helices. Thus, even in the vesicle-bound form αS has the horseshoe conformation, reveal-
ing that this conformation is intrinsic to the protein, rather than induced by the small size of micelles investigated previously. Mobility analysis of five single spin-labeled mutants showed that the membrane affinity of hex12, comprising resi-
dues 45–90, decreases with decreasing negative charge of the membrane surface, suggesting differential binding of αS to membranes. The findings reveal molecular details of the membrane-bound conformation of αS not previously obtained.

A Coarsened Network Model Reveals Allosteric Machinery
Ali Rana Atiaily, Canan Atiaily.
Sabanci University, Istanbul, Turkey.
The past decade has witnessed the development and success of coarse-grained network models of proteins for predicting many equilibrium properties related to collective modes of motion. We first use a systematic approach on a large set of globular proteins to find a basis for why the network models work well to define certain properties of the system. The analysis is based on the radial distribution function and the spectral dimensions of the membrane-bound and free forms of αS, revealing antiparallel arrangement of the helices. Thus, even in the vesicle-bound form αS has the horseshoe conformation, reveal-
ing that this conformation is intrinsic to the protein, rather than induced by the small size of micelles investigated previously. Mobility analysis of five single spin-labeled mutants showed that the membrane affinity of helix 2, comprising resi-
dues 45–90, decreases with decreasing negative charge of the membrane surface, suggesting differential binding of αS to membranes. The findings reveal molecular details of the membrane-bound conformation of αS not previously obtained.
provide a mechanism on how proteins remotely modulate bound ligands to create preferred kinetic pathways(5,6).

Sequencing Paired Reads using True Single Molecule Sequencing (tSMS) Technology

Jeff C. Reifenberger, Doron Lipson, Jennifer Colonell, Tal Raz, Bill Pierceall, John Thompson, Patrice Milos.

Helicos BioSciences Corp., Cambridge, MA, USA.

Single molecule DNA sequencing provides novel methods for interrogating DNA molecules. For example, genomic rearrangements such as insertions, deletions, and inversions that are often associated with cancers or variations within the transcriptome of specific genes can be difficult to detect with conventional sequencing strategies. Paired reads sequencing, where a spacer is inserted between two single molecule sequencing reads, offers a more viable method for detecting genomic rearrangements.

We have developed a paired reads strategy using True Single Molecule Sequencing (tSMS) in which a large number of individual templates of DNA were analyzed using a proprietary form of sequencing-by-synthesis. To create paired reads DNA strands are attached to a surface and sequenced-by-synthesis for a known number of cycles. A spacer was then added to the DNA strands in a controlled manner and then sequencing by synthesis continued for the same number of cycles.

Data on test oligonucleotides of known length and sequence demonstrate the viability of the technique and our ability to control the length of the spacer between the two reads on an individual strand. We have now extended our Paired Reads technique to biological samples, initially with a 12kb PCR product encompassing the CETP gene to demonstrate our ability to sequence the whole gene product and identify mutations which have been inserted into the CETP reference. Finally, we have utilized this novel method to examine a human placental transcriptome cDNA library to demonstrate the ability to span exon boundaries.

Self-assembly via Active Transport By Biomolecular Motors

Parag Katira, Isaac Luria, Shruti Sheshadi, Henry Hess.

University of Florida, Gainesville, FL, USA.

Modified kinesin gliding motility assays display striking self-assembly phenomena, in particular the formation of non-equilibrium structures. Biofunctional microtubules partially coated with streptavidin form “wires” and “spools” while gliding on kinesins adhered to the surface. The spool formation process was investigated in detail, and we found that the assembled spools exhibit a narrow distribution of spool diameters, and that the average diameter is an order of magnitude smaller than what would be obtained from a thermally driven assembly process. We also observe that pinning of the microtubule leading tip on the surface initiates the spool formation in 90% of the cases. By modeling the mechanism of microtubule tip buckling and the resultant microtubule spool diameter as a function of the microtubule persistence length and the number of motors attached to the microtubule, we can predict the average spool diameter and the observed spool diameter distribution. The model suggests a strong dependence of spool diameters and size distribution on the surface kinesin density. The goal of our research is to obtain a better understanding of the dynamics of this multi-agent process and its implications for self-assembly in general.

Single Cell Detection and Analysis with Asynchronous Rotation of Driven Magnetic Microparticles

Brandon H. McNaughton, Paivo Kinnunen, Rodney R. Agayan, Ron G. Smith, Alan J. Hunt, Raoul Kopelman, Roy Clarke.

University of Michigan, Ann Arbor, MI, USA.

The nonlinear rotational response of a magnetic microparticle, suspended in a viscous fluid, occurs when a driving magnetic field, used to rotate the magnetic particle, exceeds a critical frequency. Above this critical frequency, the particle is asynchronous with the external field. Shifts in this nonlinear rotational frequency of the magnetic microsphere offer a dynamic approach for the detection and quantification of nucleic acids in real time.

We present a novel method capable of stimulating nanoscale motors deep inside the body. It relies on manganese iron oxide nanoparticles targeted to the neuron’s plasma membrane to convert energy from an alternating magnetic field to local heat which opens the temperature sensitive Calcium channel TRPV1. Expressing this channel in neurons will allow us to remotely stimulate and control the neurons. We apply the method to trigger the ASH and ADL neurons in C. elegans which control the chemical avoidance reaction.

In the course of this study, we have characterized nanoscale heating and heat propagation inside cells quantifying heat conduction over nanometer distances, important knowledge to optimize the efficacy of hyperthermia treatment for cancer.

Probing Conformational Changes In Rhodopsin With Site-specific Azido Labels

Shixin Ye1, Thomas Huber2, Reiner Vogel2, Thomas P. Sakmar1.

1Rockefeller University, New York, NY, USA, 2Albert-Ludwigs-University Freiburg, Freiburg, Germany.

Transmembrane signaling via heptahelical G protein-coupled receptors (GPCRs) is essential for a cell’s communication with its environment and represents a major target for drug development. Although recent advances have provided high-resolution crystal structures of several GPCRs, understanding the conformational dynamics of receptor activation in bilayers remains paramount. Fourier-transform infrared (FTIR) difference spectroscopy has proven to be a powerful biophysical technique for structure/function relationships in the prototypical GPCR, rhodopsin. Here we report a new conceptual advance in FTIR difference spectroscopic analysis of heterologously expressed eukaryotic proteins. We demonstrate the site-directed incorporation of an IR-active unnatural amino acid, p-azido-L-phenylalanine (azidoF), into rhodopsin using amber condon suppression technology. The intense antisymmetric stretch vibration of the azido group absorbs at around 2100 cm⁻¹ in a clear spectral window devoid of other protein bands and is exceptionally sensitive to the polarity of its surroundings. Using FTIR difference spectroscopy on azidoF rhodopsin mutants, we report the changes in the electrostatic environments of selected side chains on both the cytoplasmic and extracellular receptor surfaces during the conformational transition associated with receptor activation.

Towards Mapping Domain Boundaries of Proteins

Shambaditya Saha1, Thomas D. Pollard2,3

1Dept. of Molecular Biophysics and Biochemistry, Yale University, New Haven, CT, USA, 2Dept. of Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT, USA, 3Dept. of Molecular Biophysics and Biochemistry, Yale University, New Haven, CT, USA.

GFP fluorescence from bacterial colonies expressing a polypeptide upstream of GFP depends on the solubility of the polypeptide. Inspired by this idea, we developed a method to test for the folding of any polypeptide longer than about 66 amino acids. This method bypasses the need for purification of the polypeptide to test for folding. We employed this technique to identify the independently folded domains of Mid1, a fission yeast protein of 920 amino acids.
